This map is created from information stored digitally in the BC Geographic Warehouse. The map has been structured to display on a standard computer screen or printed on 8.5" x 11" paper. Because of this, the features on the map may not be complete and up to date (cadastre, administrative boundaries and the Cheviot/no colour theme are for reference purposes only). 4d SITE INDEX
Is the average height of the dominant trees achieved at 50 years of age. Site index is the most widely used measure of forest productivity in making quantitative decisions about forest management and timber harvesting studies. Where an accurate SI cannot be obtained from measurements, it may be estimated from the site series.

4e. ESTIMATED SITE INDEX
Is the estimated site index for a stand where measurement of trees is not possible because of young age or lack of suitable trees. Estimates are based on the site series and ecosystem productivity. The estimated height in the table below are inventory conventions and not necessarily biological limits.
